Re: U.S. Patent Application
IMAGE FORMING APPARATUS
CAPABLE OF IMAGE FORMATION
IN A PLURALITY OF MODES
Attorney Docket: 05058/58201

Dear Sir:

Enclosed for filing are the following papers relating to
IMAGE FORMING APPARATUS CAPABLE OF IMAGE FORMATION IN A PLURALITY
OF MODES, Takeshi MORIKAWA, inventor:

- (1) Specification;
- (2) Executed Declaration and Power of Attorney;
- (3) Formal Drawings (16 sheets);
- (4) Certified Copy of Priority Document;
- (5) Assignment of the invention to Minolta Co., Ltd. with
Recordation Form Cover Sheet;
- (6) Check in the amount of \$40.00 to cover the Assignment
recordal fee; and
- (7) Check in the amount of \$1,142.00 to cover the filing
fee of the application.

In the event the attached checks in the amount of \$1,142.00
and \$40.00 are not received with this correspondence, are not
sufficient, or in the event additional fees are due, please
charge the required fees during the pendency of this application
(other than issue fee) to Deposit Account No. 18-1260. Please
credit any overpayment to Deposit Account No. 18-1260.

Assistant Commissioner for
Patents
September 30, 1997

TITLE OF THE INVENTION

Image Forming Apparatus Capable of Image Formation in a Plurality of Modes

BACKGROUND OF THE INVENTION

5 Field of the Invention

The present invention relates to an image forming apparatus with an image memory, and particularly to an image forming apparatus capable of changing a print mode set depending on the frame size of image data for an image data registered in the image memory with a print mode set.

10 Description of the Related Art

In a digital copying machine, a plurality of sheets of originals are read, the image data of the plurality of sheets of the originals read are once stored in an image memory, and then the image data is read from memory for printing. Such conventional digital copying machines include a digital copying machine disclosed in Japanese Patent Laying-Open No. 5-122477.

Furthermore, conventional digital copying machines can provide the economy copy for processing read image data to reduce and copy the images of a plurality of originals such that the images are arranged on the same one side of one copying sheet, the two-side copy for copying the images of originals on the front and back sides of a copying sheet, and the staple copy for stapling

at an end a plurality of copying sheets with the images of originals copied thereon.

In the economy copy, a digital copying machine reduces the images of a plurality of originals at the same 5 reduction ratio and copies the images such that they are arranged on the same one side of a copying sheet.

Accordingly, it is preferable that each original, more specifically, the frame of each read image data, has the same size. In the two-side copy, a digital copying machine 10 copies the images of originals on the front and back sides of one copying sheet. Accordingly, it is preferable that the image data of two originals copied on the front and back sides of a copying sheet have the same frame size. In the staple copy, a digital copying machine aligns a 15 plurality of copying sheets discharged from the copying machine to be stapled such that the sheets match at their ends. Accordingly, it is preferable that a plurality of copying sheets to be stapled have the same size in the direction of the alignment, i.e., the image data stored in 20 the image memory have the same frame size in the direction of the alignment.

This also applies to a printer which stores the image data of a plurality of frames (i.e., text data) into a memory and reads and prints the image data from the memory.

25 SUMMARY OF THE INVENTION

The present invention is made to address the foregoing, and one object of the present invention is to provide an image processing device and an image forming apparatus which reduce operation errors by users and are 5 thus user-friendly.

Another object of the present invention is to provide a user-friendly image forming apparatus wherein when printing cannot be performed in the staple print mode, a user will not select the staple print mode and operation 10 errors by the user are thus reduced.

Still another object of the present invention is to provide a user-friendly image forming apparatus wherein when printing cannot be performed in the two-side print mode, a user will not select the two-side print mode and 15 operation errors by the user are thus reduced.

Still another object of the present invention is to provide a user-friendly image forming apparatus wherein when printing cannot be performed in the economy print mode, a user will not select the economy print mode and 20 operation errors by the user are thus reduced.

According to an aspect of the present invention in order to achieve the aforementioned objects, an image processing device operable in a plurality of modes of operation includes a memory for storing image data, a 25 state decision unit for determining the state of the image

data stored in the memory, a display for displaying the operating condition of the image processing device, and a display controller connected to the state decision unit for displaying an operable mode of operation of a plurality of modes of operation according to the state of the image data.

5 In the image processing device according to the present invention, an operable mode of operation is displayed on the display according to the state of image data. Thus, a user can immediately decide the mode of 10 operation which is operable, and will not select an inoperable mode of operation. This reduces operation errors of the user and results in a user-friendly image processing device.

15 According to another aspect of the present invention, an image processing device operable in a plurality of modes of operation includes a memory for storing image data, a state decision unit for determining the state of the image data stored in the memory, an operation panel 20 for selecting any of the plurality of modes of operation, and a selection prohibiting controller connected to the state decision unit for prohibiting selection of an inoperable mode of operation of the plurality of modes of operation through the operation panel according to the 25 state of the image data.

In the image processing device according to the present invention, selection of an inoperable mode of operation is prohibited depending on the state of image data. Thus, a user will not select any inoperable mode of 5 operation and this reduces operation errors by the user and results in a user-friendly image processing device.

In still another aspect of the present invention, an image forming apparatus operable in a plurality of print modes includes a memory for storing image data, a printer 10 reading the image data stored in the memory for each frame for printing, a state decision unit for determining the state of the image data stored in the memory, a display for displaying the operating state of the image forming apparatus, and a display controller connected to the state 15 decision unit for displaying an operable print mode of the plurality of print modes on the display according to the state of the image data.

In the image forming apparatus according to the present invention, an operable print mode is displayed on 20 the display according to the state of image data. Thus, a user can immediately determine whether a print mode is operable and will not select an inoperable print mode. This reduces operation errors by the user and results in a user-friendly image forming apparatus.

25 Preferably, the state decision unit includes a frame-

length decision unit for determining the frame length of image data in a predetermined direction.

Still preferably, the image forming apparatus includes a finisher for stapling sheets printed in the 5 printer, the frame-length decision unit includes a device for determining whether the image data stored in the memory all have a same frame length in the predetermined direction, and the display controller includes a device for displaying on the display the staple print mode for 10 performing a staple processing by the finisher when it is determined that the image data stored in the memory all have a same frame length in the predetermined direction.

In the image forming apparatus according to the present invention, whether or not printing in the staple 15 print mode can be provided is determined depending on the frame length of image data in a predetermined direction. When printing can be provided in the staple print mode, the print mode is displayed on the display. Thus, a user can immediately determine whether printing can be provided 20 in the staple print mode, and will not select the staple print mode when printing cannot be provided in the print mode. This reduces operation errors by the user and results in a user-friendly image forming apparatus.

Preferably, the state decision unit includes a frame- 25 size decision unit for determining the frame size of image

data.

Still preferably, the frame-size decision unit includes a device for determining whether the image data stored in the memory all have a same frame size, and the 5 display controller includes a device for displaying on the display the two-side print mode for printing image data on the both sides of a sheet when the image data stored in the memory are determined as all having a same frame size.

In the image forming apparatus according to the 10 present invention, whether or not printing can be provided in the two-side print mode is determined depending on the frame size of image data. When printing can be provided in the two-side print mode, the print mode is displayed on the display. Thus, a user will not select the two-side 15 print mode when printing cannot be provided in the print mode. This reduces operation errors by the user and results in a user-friendly image forming apparatus.

Still preferably, the frame-size decision unit includes a device for determining whether the image data 20 stored in the memory all have a same frame size, and the display controller includes a device for displaying on the display the economy mode for printing image data of a plurality of frames on one side of a sheet when the image data stored in the memory are determined as all having a 25 same frame size.

In the image forming apparatus according to the present invention, when printing in the economy print mode can be provided depending on the frame size of image data, the print mode is displayed on the display. Thus, a user 5 can immediately determine whether printing can be provided in the economy print mode, and will not select the economy print mode when printing cannot be provided in the print mode. This reduces operation errors by the user and results in a user-friendly image forming apparatus.

10 In still another aspect of the present invention, an image forming apparatus operable in a plurality of print modes includes a memory for storing image data, a printer reading the image data stored in the memory for each frame for printing, a state decision unit for determining the 15 state of the image data stored in the memory, an operation panel for selecting any of the plurality of print modes, and a selection prohibiting controller connected to the state decision unit for prohibiting selection of any inoperable print modes of the plurality of print modes 20 through the operation panel according to the state of the image data.

In the image forming apparatus according to the present invention, selection of any inoperable print mode is prohibited depending on the state of image data. Thus, 25 a user will not select any inoperable print mode. This

reduces operation errors by the user and results in a user-friendly image forming apparatus.

Preferably, the image forming apparatus includes a finisher for stapling sheets printed in the printer, the 5 state decision unit includes a device for determining whether the image data stored in the memory have different frame sizes, and the selection prohibiting controller includes a device for prohibiting the staple print mode for providing a staple processing by the finisher from 10 being selected through the operation panel when the image data stored in the memory are determined as having different frame sizes.

In the image forming apparatus according to the present invention, selecting the staple print mode is 15 prohibited depending on the frame size of image data. Thus, a user will not select the staple print mode when printing cannot be provided in the print mode. This reduces operation errors by the user and results in a user-friendly image forming apparatus.

20 Preferably, the state decision unit includes a device for determining whether the image data in the memory have different frame sizes, and the selection prohibiting controller includes a device for prohibiting selecting through the operation panel the two-side print mode for 25 printing image data on the both sides of a sheet when the

image data in the memory are determined as having different sizes.

In the image forming apparatus according to the present invention, selecting the two-side print mode is prohibited depending on the frame size of image data. Thus, a user will not select the two-side print mode when printing cannot be provided in the print mode. This reduces operation errors by the user and results in a user-friendly image forming apparatus.

10 Preferably, the state decision unit includes a device for determining whether the image data stored in the memory all have a same frame size, and the selection prohibiting controller includes a device for prohibiting selecting through the operation panel the economy print mode for printing the image data of a plurality of frames on one side of a sheet when the image data stored in the memory are determined as all having a same frame size.

In the image forming apparatus according to the present invention, selecting the economy print mode is prohibited depending on the frame size of image data. Thus, a user will not select the economy print mode when printing cannot be provided in the print mode. This reduces operation errors by the user and results in a user-friendly image forming apparatus.

25 In still another aspect of the present invention, an

image forming apparatus operable in a plurality of print modes includes a memory for storing a print job including image data of no less than one frame, a print job selecting unit for selecting one of print jobs stored in 5 the memory, a state decision unit for determining the state of the image data included in a print job selected at the print job selecting unit, a printer for printing the image data included in the print job selected at the print job selecting unit, a display for displaying the 10 operating state of the image forming apparatus, and a display controller connected to the state decision unit for displaying on the display an operable print mode of the plurality of print modes depending on the state of image data.

15 In the image forming apparatus according to the present invention, an operable print mode is displayed on the display depending on the state of image data. Thus, a user can immediately determine whether a print mode is operable and will not select any inoperable print modes. 20 This reduces operation errors by the user and results in a user-friendly image forming apparatus.

In still another aspect of the present invention, an image forming apparatus operable in a plurality of print modes includes a memory for storing a print job including 25 image data of no less than one frame, a print job

selecting unit for selecting one of print jobs stored in the memory, a state decision unit for determining the state of the image data included in a print job selected at the print job selecting unit, a printer for printing
5 the image data included in the print job selected at the print job selecting unit, an operation panel for selecting any of the plurality of print modes, and a selection prohibiting controller connected to the state decision unit for prohibiting selecting through the operation panel
10 an inoperable print mode of the plurality of print modes depending on the state of the image data included in a print job.

In the image forming apparatus according to the present invention, selecting an inoperable print mode is
15 prohibited depending on the state of image data. Thus, a user will not select any inoperable print modes. This reduces operation errors by the user and results in a user-friendly image forming apparatus.

The foregoing and other objects, features, aspects
20 and advantages of the present invention will become more apparent from the following detailed description of the present invention when taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

DESCRIPTION OF THE PREFERRED EMBODIMENTS

10 Referring to Fig. 1, a digital copying machine 1 as one embodiment of the present invention includes an image reader IR, a printer PRT, and an operation panel OP (shown in Fig. 2) mounted to an upper portion of the body.

15 Image reader IR includes: a scan system 10 for scanning to read an original placed on an original supporting glass 18; an image signal processing unit 20 for processing an image signal for an image obtained by reading the original; a memory unit 30 for storing as image data the image signal for the image of the original
20 processed by image signal processing unit 20; and an automatic document feeder 500 pivotably mounted on upper side of image reader IR with a back side thereof as a fulcrum.

25 Scan system 10 is a line scanning, image reading mechanism, in which scanner 19 provided with an original

illuminating lamp 11 and a mirror 12 is moved for scanning in the direction indicated by the arrow in the figure to successively illuminate an image plane of an original placed on original supporting glass 18 and the reflected 5 light is projected onto an image sensor 16 via fixed mirrors 13a and 13b and projection lens 14. Image sensor 16 is a line sensor having a plurality of photoelectric conversion elements arranged in a line, and each photoelectric conversion element (i.e., pixel) outputs an 10 image signal depending on the quantity of light received.

Image signal processing unit 20 converts the image signal output from each photoelectric conversion element into a digital signal for various signal processings.

Memory unit 30 stores the digital signal as image data.

15 Image signal processing unit 20 and memory unit 30 will be detailed later.

Original transport device 500 includes a sheet feeding roller 501, a sorting roller 502, a sorting pad 503, an intermediate roller 504, a registering roller 505, 20 a transport belt 506, a reversing roller 507, a switching claw 508, a sheet feeding roller 509, an original stacker 510, an original discharging tray 511, an original scale 512, an original sensor SE50 for detecting whether an original is present, an original size sensor S51, and a 25 discharge sensor SE52.

In automatic document feeder 500, an original set on original stacker 510 is transported by sheet feeding roller 501, sorting roller 502, sorting pad 503, intermediate roller 504, registering roller 505 and 5 transport belt 506 onto original supporting glass 18. Furthermore, in automatic document feeder 500, a read original is discharged by transport belt 506 and discharging roller 509 onto original discharging tray 511.

In copying a plurality of originals, for example, an 10 operator sets the originals by stacking them on original stacker 510 which their front sides facing upward. The originals on original stacker 510 are successively drawn one by one from the bottom original and precisely set at the reading position on original supporting glass 18 with 15 the front sides facing downward. For a one-side original, which has an image only on one side thereof, when image reader IR has finished reading the original, the original is transported in the left direction in Fig. 1 and discharged onto original discharging tray 511 with the 20 front side facing upward. For a two-side original, which has images on the both sides thereof, an original transported in the left direction after image reader IR has finished reading the front side is turned over by reversing roller 507 and returned to the reading position 25 on original supporting glass 18. Then, the original has

its back side read and is then again transported in the left direction and discharged onto original discharging tray 511.

5 Printer PRT prints an image of an original on a copying sheet by electrophotography process based on image data transferred from image reader IR.

An operation of printer PRT will now be described. Printing processing unit 40 reads image data from memory unit 30 and provides the image data to a print head 60. In 10 print head 60, a semiconductor laser 62 is driven according to the image data and a laser beam modulated according to the image data is emitted. The laser beam is deflected by a polygon mirror 65 and guided onto an exposure position on a photoreceptor drum 71 via a lens 69 15 and various mirrors 67a, 68 and 67c.

Photoreceptor drum 71 is carried such that it can be rotatably driven in the counterclockwise direction in the figure. As photoreceptor drum 71 rotates in such a manner, the electrophotography process is performed. More 20 specifically, photoreceptor drum 71 has its surface uniformly charged by means of a corona charger 72, and has the exposure position exposed to the aforementioned laser beam. The exposure to the laser beam allows the formation of an electrostatic latent image corresponding to an image 25 of an original on photoreceptor drum 71. The electrostatic

latent image is developed by a developing device 73 to provide a toner image which is transferred at a transfer position by a transfer charger 74 from photoreceptor drum 71 to a copying sheet. After the toner image is 5 transferred, the residual toner on photoreceptor drum 71 is collected by a cleaning device 76.

Copying sheets are housed in cassettes 80a and 80b depending on the size. The copying sheets are successively sent out one by one by a sheet feeding roller provided at 10 an upper portion of each cassette, and transported to the transfer position via a timing roller 82 for transfer of a toner image. Then, the copying sheet with the toner image transferred thereon is separated from photoreceptor drum 71 by a separation charger 75 and sent to a fixing roller 15 84 by a transport belt 83. After the toner image is fixed on the copying sheet, the sheet is discharged by a discharging roller 85 to the outside of the machine.

It should be noted that the sizes of copying sheets housed in cassettes 80a and 80b are detected by sheet-size 20 detection sensors SE11 and SE12, respectively.

The printing sheets discharged to the outside of the machine are transported to a finisher 600, which has switching claws 601, 604 and 605 operating depending on the copy mode to guide the copying sheets to discharging 25 tray 621 or 631 or a stapling tray 641.

When the staple print mode is set, finished copying sheets are guided to and temporarily stored on stapling tray 641. When all of the copying sheets are stored, they are stapled by staple unit 642 and the set of the stapled 5 copying sheets is discharged onto discharging tray 651 via transport roller 643.

When the two-side print mode is set, a copying sheet is switched back by transport roller 603 and again sent into the machine. The copying sheet is transported via 10 transport roller 86a, 86b, and 86c to the transfer position for copying on the back side.

The aforementioned digital copying machine 1 is operable in various print modes. Operations of digital copying machine 1 in the various print modes will now be 15 described.

In the one-side print mode, digital copying machine 1 successively copies images read from originals on one side of copying sheets.

In the two-side print mode, digital copying machine 1 20 successively copies images read from originals on the front and back sides of copying sheets.

The economy print mode includes the 2-in-1 mode and the 4-in-1 mode. In the 2-in-1 mode, digital copying machine 1 copies read originals with two of them arranged 25 on one side of one copying sheet. In the 4-in-1 mode,

digital copying machine 1 copies read originals with four of them arranged on one side of one copying sheet.

In the staple print mode, digital copying machine 1 staples finished copying sheets on stapling tray 641, as 5 described above.

An operation of copying machine 1 will now be described with reference to Figs. 2-4.

Referring to Fig. 2, a liquid crystal touch panel 91 is provided at the center of operation panel OP. Liquid 10 crystal touch panel 91 displays the state of digital copying machine 1 as well as displays various touch keys for inputting copying conditions so that inputs by an operator are accepted via the touch keys. Provided on the right side of liquid crystal touch panel 91 are a ten-key 15 92 for inputting numerical conditions, e.g., copying magnification and the number of sheets to be copied, and a clear key 93 for returning a numerical condition to a standard value. Provided thereunder are a panel reset key 94 for initializing various print modes, a stop key 95 for 20 providing a direction that copying is stopped, and a start key 96 for providing a direction that copying is started.

Operation panel OP further includes: an economy-copy designating key 97 for alternately selecting setting the 2-in-1 mode, setting the 4-in-1 mode and canceling the 25 economy mode each time it is pressed; a one-side/two-side

selecting key 98 for alternately selecting setting the two-side print mode and setting the one-side print mode each time it is pressed; a finishing key for alternately selecting setting the staple mode and canceling the staple mode each time it is pressed; and an original key 99a for alternately selecting setting the original mixed mode and setting the original non-mixed mode each time when it is pressed.

The original mixed mode is set by an operator when at least one of a plurality of originals is different in size from the other originals in copying the plurality of originals through a series of copying operations (a job) successively performed in response to one direction that copying is started. The original non-mixed mode is set by an operator when a plurality of originals have a same size in copying all the originals through one job. It should be noted that the originals placed on original stacker 510 of automatic document feeder 500 are all copied in a series of copying operations. Thus, an operator sets the original mixed mode when he or she sets on original stacker 510 a plurality of originals having different sizes mixed, and sets the original non-mixed mode when he or she sets originals having a same size.

Furthermore, the present digital copying machine 1 is set in one of the multijob mode and the memory recall mode

by means of a dip switch DP (not shown) provided in digital copying machine 1.

When the multijob mode is set, digital copying machine 1 can use memory unit 30 to simultaneously process 5 a plurality of jobs in parallel. More specifically, one job is comprised of the operation for reading an original and the operation for printing the read image data. Thus, storing the image data of a read original into the memory allows an operator to execute the reading of the group of 10 other originals and store the image data into memory unit 30 while digital copying machine 1 reads the image data of the original from memory unit 30 and prints it. Although memory unit 30 has a capacity sufficient to store image data of a plurality of jobs, the image data of originals 15 which have been printed are successively erased from memory unit 30 so that a large number of jobs are stored.

When the memory recall mode is set, digital copying machine 1 does not erase from memory unit 30 the image data of a job which has been printed unless any specific 20 command is issued. This allows an operator to again read from memory unit 30 the image data which has been printed and print it. In this printing, the operator can change the previous print mode. For example, a copying is initially performed in the two-side print mode and then 25 the print mode can be changed to the 2-in-1 mode for

another copying. Since the image data within memory unit 30 is not erased and thus held in the memory recall mode after printing is completed, it is difficult that digital copying machine 1 stores the image data of other jobs.

5 Thus, digital copying machine 1 cannot provide the simultaneous, parallel processing of a plurality of jobs, which can be provided in the multijob mode, in the memory recall mode.

10 The displaying manner and inputting operation on liquid crystal touch panel 91 in the multijob mode will now be described with reference to Figs. 2-3.

15 A screen Q10 is displayed on liquid crystal touch panel 91, as shown in Fig. 2, while image data is read from memory 30 and being printed. When an operator presses a touch key "CONFIRM" displayed on screen Q10, a job confirmation screen shown in Fig. 3(A) is displayed. The job confirmation screen informs the operator of any job registered in memory unit other 30 than the job being currently printed by displaying the job ID number for identifying the registered job. The example shown in Fig. 20 3(A) shows the condition that three jobs with job ID Nos. 1, 2 and 3 are registered in memory unit 30 and wait for being printed. When a touch key "RESERVE" on the job confirmation screen is pressed, a reservation screen 25 appears as shown in Fig. 3(C). The reservation screen

displays a touch key for setting a copying condition for a new job. When an operator sets a copying condition on the screen and presses start key 96, a new job is added to the job being currently printed and the three jobs Nos. 1-3
5 waiting for being printed and an original of the new job is read.

When any of the jobs waiting for being printed is designated on the job confirmation screen shown in Fig. 3(A) and a touch key "CHANGE" is then pressed, such a mode
10 changing screen as shown in Fig. 3(B) appears. The mode changing screen displays an optional print mode for the designated job waiting for being printed. The example shown in Fig. 3(B) shows that the two-side print mode, the economy print mode and the staple print mode are available.
15 Any of the displayed print modes touched by the operator is set as the print mode for the designated job. It should be noted that an optional mode is automatically determined and displayed depending on the frame size of the image data included in a designated job, which processing will
20 be detailed later. When the operator presses a touch key "OK" on the mode changing screen, the screen returns to screen Q10 shown in Fig. 2.

The displaying manner and inputting operation on liquid crystal touch panel 91 in the memory recall mode
25 will now be described with reference to Fig. 4.

When the memory recall mode is set and a printing of a job is completed, liquid crystal touch panel 91 displays a copy standby screen indicating that copying is in a standby state, as shown in Fig. 4(A). When the operator 5 presses a touch key "RECALL" on liquid crystal touch panel 91, the screen for changing the memory recall mode appears as shown in Fig. 4(B). The screen for changing the memory recall mode displays any optional print modes for the image data held in memory unit 30 after printing of the 10 image data is completed. The example shown in Fig. 4(B) indicates that the two-side print mode, the economy print mode and the staple print mode are available. Any of the displayed print modes touched by the operator is set as the print mode for the job which has been printed. When 15 the operator then presses start key 96, digital copying machine 1 again reads the image data stored in memory unit 30 and prints the data in the selected print mode. It should be noted that an optional print mode is automatically determined and displayed depending on the 20 frame size of the image data included in a designated job, which processing will be detailed later. When a touch key "OK" is pressed on the screen for changing the memory recall mode, the screen is returned to screen Q10 shown in Fig. 2. When a touch key "CLEAR" is pressed on the screen 25 for changing the memory recall mode, the image data stored

in memory unit 30 is erased after the image data has been printed, and a new original reading is allowed.

In order to start to read a new original immediately after a printing of a job is completed, the operator sets 5 the mode for the next job without pressing the "RECALL" key on the copy standby screen and then presses start key 96. The reading of the original is thus started.

A control unit 100 for providing various controls of copying machine 1 will now be described with reference to 10 Figs. 5 and 6. Control unit 100 includes eight CPUs (Central Processing Units) 101-108, ROMs (Read Only Memories) 111-118 for storing programs performed in CPUs 101-108, respectively, and RAMs (Random Access Memories) 121-128 for storing parameters and the like. CPU 106 is 15 provided within memory unit 30.

CPU 101 controls signal inputs from various operation keys on operation panel OP as well as displaying on operation panel OP. CPU 102 controls various portions of image signal processing unit 20. CPU 103 controls the 20 driving of scan system 10. CPU 104 controls printer PRT including printing processing unit 40. CPU 105 provides the general timing adjustment for control unit 100 and a processing for setting modes of operation. Thus, CPU 105 performs serial communication with the other CPUs to 25 transmit and receive commands and reports required for

control. CPU 106 controls the storing and reading of image data. CPU 107 controls the transporting of originals by automatic document feeder 500. CPU 108 controls finisher 600.

5 Referring to Fig. 7, memory unit 30 includes an input page memory 301, a compressor 302, a code memory 303, a decompressor 304, an output page memory 305, a rotator 306, CPU 106, ROM 116 and RAM 126.

10 In reading an original, image data D2 read by image reader IR is transferred to input page memory 301, compressed by compressor 302 for each page and transferred to code memory 303.

15 In printing, compressed image data stored in code memory 303 is decompressed by decompressor 304. If image rotation is required, rotation processing is provided in the decompression by rotator 306 for each page.

20 The decompressed image data is transferred to output page memory 305 which transfers image data D3 to printing processing unit 40. The image transfers indicated by the arrows in the figure are independent from one another and can be operated in parallel to improve copying speed. Each image data is DMA-transferred by a DMA controller (not shown).

25 CPU 106 controls memory unit 30 according to a program stored in ROM 116. RAM 126 stores a parameter and

the like required for operating the program.

Code memory 303 for temporarily storing image data of an original is managed by a management table provided within RAM 126.

5 The management table will now be described with reference to Fig. 8. Image data which is compressed after an original is read is managed for each print job. One job stores a plurality of pages which are divided. Thus, the management table includes a page management information table (T-2) for storing the divided information for each page and a job management information table (T-1) for storing the information for each job.

10 The job management information table (T-1) stores a job ID number, the registration state of the job, the storing location in the page management information table corresponding to the job, and the number of copies to be made, the set print mode and any optional print mode for the job, and the like. The page management information table (T-2) stores the length in the main scanning direction and the length in a subscanning direction of the image data frame of a read original, and the storing location of compressed image data.

15 It should be noted that the registration state of a job stored in the job management information table (T-1) 20 is the information indicating the read state of a job,

i.e., whether the reading of an original is completed.

In reading an original according to a direction from CPU 105, CPU 106 reads image data from input page memory 301 while forming information for the management table.

5 CPU 106 also controls compressor 302 to store compressed image data into code memory 303.

In printing image data, CPU 106 refers to the information in the management table to read the compressed image data from code memory 303. In erasing the 10 information in the management table, the multijob mode and the memory recall mode are different from each other as follows:

(1) in the multijob mode, the information of interest in the management table is erased when compressed image 15 data has been read based on the information of the page of interest and printed by the number of sheets and the number of copies designated by an operator; and

(2) in the memory recall mode, the information of interest in the management table is erased when an 20 operator presses the "CLEAR" key on the screen for changing the memory recall mode shown in Fig. 4B displayed on liquid crystal touch panel 91 and a direction that a job is cleared or a direction that a new original is read is provided.

25 Referring to Figs. 9 and 10, an operation sequence of

digital copying machine 1 in original reading and printing will now be described mainly with respect to request commands (Q) reporting signals (A) and a stream of image data among CPUs 101-106.

5 Referring to Fig. 9, in the original reading operation, read image data is transferred from image signal processing unit 20 to memory unit 30.

First, CPU 105, which controls the general sequence, issues a memory preparation command to CPU 106.

10 Responsively, CPU 106 sets for an internal hardware a bus connection state for transferring image data D2 from image signal processing unit 20 to memory unit 30. When the setting is completed and the preparation is completed, CPU 106 transmits to CPU 105 a signal for reporting the memory 15 preparation has been completed.

When CPU 105 issues a read command to CPUs 106 and 102, CPU 102 issues a scan command to CPU 103.

CPU 103 starts scanning. When scanner 19 reaches an 20 image region, read data (image data D2) is transferred from image signal processing unit 20 to memory unit 30 according to an image processing mode set by CPU 102.

When the scanning is completed and CPU 102 and CPU 106 transmit a signal for reporting that a reading has been completed, CPU 105 issues a data compression command 25 to CPU 106. CPU 106 responsively initiates various

portions, e.g., input page memory 301, compressor 302 and code memory 303. This allows the compression processing and coded data (compressed image data) is stored in code memory 303. When the compression processing is completed, 5 CPU 106 notifies CPU 105 that a compression has been completed by means of a signal for reporting that a compression has been completed.

Referring to Fig. 10, in the printing operation, image data is read from code memory 303 and a copied image 10 is printed on a copying sheet according to the image data.

First, CPU 105 issues to CPU 106 a decompression command to request data decompression. CPU 106 initiates various portions, e.g., code memory 303, decompressor 304, rotator 306 and output page memory 305. A decompression 15 processing is thus performed an image data is written to output page memory 305.

When the decompression processing is completed, CPU 106 transmits to CPU 105 a signal for reporting that the decompression has been completed.

20 CPU 105 issues to CPU 106 a memory preparation command for reading the image data from output page memory 305. Responsively CPU 106 sets for the internal hardware the bus connection state, rotation processing and the like for outputting image data D3 from output page memory 305 25 to printing processing unit 40.

When the aforementioned setting is completed and CPU 105 receives a signal for reporting that the memory preparation has been completed, CPU 105 issues a print command to CPUs 106 and 104. CPU 104 sends to CPU 105 a sheet-feeding reporting signal for informing CPU 105 of the transport state of a copying sheet. Then, image data D3 read from input page memory 305 is output to printing processing unit 40 and printing is performed.

When the printing is completed, CPU 106 transmits to CPU 105 a signal for reporting that the printing has been completed. CPU 104 transmits to CPU 105 a signal for reporting that the printing has been completed and a signal for reporting that an eject has been completed. When CPU 105 receives these reports in the multijob mode, CPU 105 issues a memory clear command to CPU 106 and erases the image data which has been printed.

Referring to the flow charts shown in Figs. 11-16, an operation of digital copying machine 1 will now be more specifically described mainly with respect to a control characterized according to the present invention.

A flow of a processing by CPU 101, which is responsible for control of operation panel OP, will now be described with reference to Fig. 11. Upon power-on, CPU 101 first initializes RAM 121, a register and the like (#11). Then, CPU 101 repeatedly performs the setting of an

internal timer which defines the length of one routine (#12), the key input processing for accepting key operations (#13), the panel display processing for providing displayings according to operations (#14), other processings (#15) and the decision-making on whether the internal timer has expired (#16). Also, CPU 101 appropriately provides interruption for communication with the other CPUs.

Referring to Fig. 12, CPU 105, which directs the control of digital copying machine 1, provides initialization (#51), and then repeatedly performs starting an internal timer (#52), the input data analysis processing for checking input data from the other CPUs (#53), the mode setting processing for setting a mode of operation according to the content of a setting on the operation panel (#54), the original reading processing (#55), the print processing (#57), the output data setting for allowing a command to standby at a communication port (#58), other processings (#59) and the decision-making on whether the internal timer has expired (#60).

The original reading processing (#55) shown in Fig. 12 will now be detailed referring to Fig. 13. This routine provides reading of originals by the image reader.

First, CPU 105 checks whether an original is present on original stacker 510 (#101). If any original is present

(YES at #101), CPU 105 determines the current reading state (#103). If the original is not being read (NO at #103), CPU 105 inquires of CPU 101 whether a request to start a new original reading has already been received via
5 the start key on operation panel OP (#105). If a request to start the reading is present (YES at #105), CPU 105 updates a job ID number (#107), sets a reading flag for indicating that a reading is being performed (#108), and controls a reading sequence (#109). In the reading
10 sequence control, CPU 105 communicates the aforementioned commands and reports with CPUs 106, 102 and 103 to compress the image data of a plurality of originals for each page and successively register the image data in the aforementioned management table and code memory 303.

15 The size of an original is detected by the aforementioned original-size sensor SE51, and the information on the detected size of the original is transmitted by the reading sequence control of #109 from CPU 107 to CPU 105.

20 When an operator sets the original mixed mode, CPU 105 provides the size detection for all originals and the lengths of the originals detected in the main and subscanning directions are registered in the aforementioned management table. When an operator sets the
25 original non-mixed mode, the size detection is provided

only for the first original and the sizes of the following originals are not detected and thus the originals are successively read according to the size of the first original.

5 When there is not a request to start a new original reading from operation panel OP (NO at #105), CPU 105 completes the original reading processing (#55) and successively provides the print processing (#57).

10 If the current read operation is in a reading state (i.e., if the reading flag is set) (YES at #103), CPU 105 provides the reading sequence control (#109).

15 When there remain no originals (NO at #101) and the reading flag is still set (YES at #111), CPU 105 determines that the reading of all of the originals has been completed, cancels the reading flag (#113) and provides the print job registration processing described later (#125).

20 The print job registration (#125) shown in Fig. 13 will now be more specifically described with reference to Fig. 14.

First, CPU 105 determines whether the job for which a reading operation is determined as having been completed at #101 and #111 is set in the original mixed mode or the original non-mixed mode (#200). If it is set in the original mixed mode (YES at #200), CPU 105 determines

whether the originals read all have the same size in the processings at #201-205.

As has been described above, the original mixed mode is set by an operator when a plurality of originals 5 includes at least one original which is different in size from the other originals in copying the plurality of originals in one job. However, an operator can inadvertently set the original mixed mode when all originals have the same size, and thus the sizes of 10 originals are determined in the aforementioned processings.

CPU 105 reads the page management information table (T-2) of the management table and determines whether the image data of all read originals have a same length in the main scanning direction (#201). If the data all have the 15 same length in the main scanning direction (YES at #201), printing can be executed in the stable print mode while image data having a different length in the subscanning direction is mixed. Thus, CPU 105 sets a flag for providing a permission to change a print mode to the 20 staple print mode (#203). CPU 105 then determines whether the image data of the originals all have a same length in the subscanning direction (#205). If the image data all have a same length in the subscanning direction (YES at #205), the image data of the originals all have a same 25 frame size and a print mode can be changed to the economy

print mode and the two-side print mode. Thus, CPU 105 sets a flag for providing a permission to change to economy copying and a flag for providing a permission to change to two-side copying (#207 and #209).

5 If a mode is the original non-mixed mode (NO at #200), the originals are assumed to all have a same size and CPU 105 sets the flag for providing a permission to change a print mode to the staple print mode, the flag for providing a permission to change to economy copying, and a 10 flag for providing a permission to change to two-side copying (#212).

15 It should be noted that printing in the one-side print mode can constantly be performed independently of the sizes of originals and thus does not require managing the enabling and disabling of the changes by means of the flags, as is in the other print modes.

20 Then, CPU 105 registers the information on the above optional print modes into the job management information table (T-1) depending on the states of the flags. CPU 105 also registers in the job management information table (T-1) job registration information indicating that reading is completed for all of originals (#211).

25 The print processing (#57) shown in Fig. 12 will now be more specifically described with reference to Fig. 15. In this routine, CPU 105 reads image data from code memory

303 and prints the image data.

CPU 105 determines whether printing is being performed (#301). If printing is being performed (YES at #301), CPU 105 determines whether all pages of a print job being currently processed (referred to as "the current print job" hereinafter) have been printed (#303). If the printing is completed (YES at #303), CPU 105 determines based on the information in the management table whether any unprocessed print job is present (#305). If any unprocessed print job is present (YES at #305), CPU 105 updates the current print job (#307) and sets the printing flag which indicates that printing is being performed (#309). If no unprocessed job is present (NO at #305), CPU 105 cancels the printing flag (#321). CPU 105 communicates the aforementioned commands and reports with CPUs 106 and 104 while referring to the aforementioned management table to successively read the image data corresponding to the current print job from code memory 303 for each page and apply the decompression and printing processings to the image data (#311). If the printing of the current print job is not completed (NO at #303), CPU 105 immediately performs the print sequence control (#311). If printing is not being performed (NO at #301), CPU 105 provides the processing of #305 and the subsequent processings.

25 Referring to Fig. 16, the key input processing (#13)

shown in Fig. 11 will now be more specifically described, which provides the control of the operation panel with respect to mode changing while CPU 101 is in a printing standby state. First, CPU 101 determines whether the 5 current mode is the multijob mode (#401). If it is the multijob mode (YES at #401), CPU 101 determines whether printing is being performed (#403). If printing is being performed (YES at #403), CPU 101 determines whether reading is being performed (#405). If reading is not being 10 performed, any of Q10 shown in Fig. 2 and the screens shown in Figs. 3A, 3B and 3C is displayed. A description for each of the screens will now be provided.

(1) When the screen which indicates that printing is being performed is displayed (YES at #420, Q10 shown in 15 Fig. 2), CPU 101 determines whether the "CONFIRM" key has been pressed on liquid crystal touch panel 91 (#422). If it has been pressed (YES at #422), CPU 101 reads the job ID number of a job originals for which have all been read and which is registered in the management table (#424) to 20 switch the screen to the job confirmation screen shown in Fig. 3 (#426). Thus, the job ID number of a job for which reading is completed and which is waiting for being printed is displayed on the screen as shown in Fig. 3(A).

(2) When the job confirmation screen is displayed (NO 25 at #420, YES at #430, Fig. 3(A)), CPU 101 determines

whether the "RESERVE" key has been pressed on liquid crystal touch panel 91 (#432). If it has been pressed, CPU 101 changes the screen to the reservation screen (Fig. 3(C)) (#434).

5 If the "CHANGE" key has been pressed (NO at #432, YES at #436), CPU 101 reads any optional print modes from the data in the job management information table to switch the screen to the mode changing screen (#438 and #440). Thus, an optional print mode(s) are displayed on the screen.

10 (3) When the mode changing screen is displayed (NO at #430, YES at #450, Fig. 3(B)), CPU 101 determines whether any of the touch keys corresponding to optional print modes displayed has been pressed (#452). If any touch key has been pressed (YES at #452), CPU 101 changes the print mode for a job to the print mode corresponding to the pressed touch key and updates the job information management table (#454). In other words, any print modes that cannot be optional are not displayed on the screen. Changing to those print modes is thus prohibited.

15 20 CPU 101 also determines whether the "OK" key has been pressed (#456). If it has been pressed, CPU 101 switches the screen to screen Q10 indicating that printing is being performed (#458).

25 The control of the operation panel on the mode changing screen during printing standby in the multijob

mode is provided as described above. On the contrary, when the memory recall mode is selected (NO at #401), the processing for controlling the displaying of the memory recall mode is provided (#401a). The processing is similar 5 to the control of the displaying in the multijob mode (#403-#458), determining which touch keys are pressed on each screen shown in Figs. 4(A) and 4(B) and performing mode changing and screen switching according to the decision results. Needless to say, when the "RECALL" key 10 is pressed on the screen shown in Fig. 4(A), CPU 101 reads any optional print modes from the data in the job management information table and displays only the optional print modes on the screen. Changing to the other print modes is thus prohibited.

15 When the aforementioned processing is completed, CPU 101 provides other input processings by means of the ten-keys (#410), and a processing for switching to other screens (#412).

Thus, the digital copying machine 1 described above 20 allows only optional print modes to be displayed on the screen. This prevents a user from changing a print mode to a print mode which is not optional, reduces operation errors and thus improves the operability of digital copying machine 1.

25 Although the present invention has been described and

illustrated in detail, it is clearly understood that the
same is by way of illustration and example only and is not
to be taken by way of limitation, the spirit and scope of
the present invention being limited only by the terms of
5 the appended claims.

WHAT IS CLAIMED IS:

1. An image processing device operable in a plurality of modes of operation, comprising:

a memory for storing image data of a plurality frames;

5 state decision controller for determining a state of said image data stored in said memory for each frame;

a display for displaying an operating state of said image processing device; and

10 a display controller for displaying on said display an operable mode of operation of said plurality of modes of operation according to the state of said image data.

2. The image processing device according to claim 1, wherein said state decision controller determines a length of a frame of said image data in a predetermined direction.

3. The image processing device according to claim 1, wherein said state decision controller determines a frame size of said image data.

4. An image processing device operable in a plurality of modes of operation, comprising:

a memory for storing image data of a plurality of

frames;

5 state decision controller for determining a state of
said image data stored in said memory for each frame;
an operation panel for selecting any of said
plurality of modes of operation; and
a selection prohibiting controller for prohibiting
10 selecting an inoperable mode of operation of said
plurality of modes of operation through said operation
panel according to the state of said image data.

5. The image processing device according to claim 4,
wherein said state decision controller determines a length
of a frame of said image data in a predetermined direction.

6. The image processing device according to claim 4,
wherein said state decision controller determines a frame
size of said image data.

7. An image forming apparatus operable in a plurality
of print modes, comprising:

a memory for storing image data of a plurality of
frames;
5 a printer for reading said image data stored in said
memory for each frame and for printing;
state decision controller for determining a state of

10 said image data stored in said memory for each frame;
 a display for displaying an operating state of said
image forming apparatus; and
 a display controller for displaying on said display
an operable print mode of said plurality of print modes
according to the state of said image data.

8. The image forming apparatus according to claim 7,
wherein said state decision controller determines a length
of a frame of said image data in a predetermined direction.

9. The image forming apparatus according to claim 8,
further comprising a finisher for stapling sheets printed
by said printer, wherein:

5 said frame-length decision controller determines
whether said image data stored in said memory all have a
same frame length in said predetermined direction; and
 said display controller displays a staple print mode
on said display when it is determined that said image data
stored in said memory all have a same frame length in said
10 predetermined direction, said staple print mode being
provided so that said finisher provides a staple
processing.

10. The image forming apparatus according to claim 7,

wherein said state decision controller determines a frame size of said image data.

11. The image forming apparatus according to claim 10, wherein:

5 said frame-size decision controller determines whether said image data stored in said memory all have a same frame size; and

10 said display controller displays a two-side print mode on said display when it is determined that said image data stored in said memory all have a same frame size, said two-side print mode being provided for printing said 10 image data stored in said memory on both sides of a sheet.

12. The image forming apparatus according to claim 10, wherein:

5 said frame-size decision controller determines whether said image data stored in said memory all have a same size; and

10 said display controller displays an economy print mode on said display when it is determined that said image data stored in said memory all have a same frame size, said economy print mode being provided for printing said 10 image data of a plurality of frames on a same side of a sheet.

13. An image forming apparatus operable in a plurality of print modes, comprising:

a memory for storing image data of a plurality of frames;

5 a printer for reading said image data stored in said memory for each frame and for printing;

state decision controller for determining a state of said image data stored in said memory;

10 an operation panel for selecting any of said plurality of print modes; and

a selection prohibiting controller for prohibiting selecting an inoperable print mode of said plurality of print modes through said operation panel according to the state of said image data.

14. The image processing device according to claim 13, further comprising a finisher for stapling sheets printed by said printer, wherein:

5 said state decision controller determines whether said image data stored in said memory includes said image data different in frame size from other said image stored in said memory; and

10 said selection prohibiting controller prohibits selecting a staple print mode through said operation panel when it is determined that said memory includes said image

data different in frame size from other said image data stored in said memory, said staple print mode being provided so that said finisher provides a staple processing.

15. The image forming apparatus according to claim 13, wherein:

5 said state decision controller determines whether said memory stores said image data different in frame size from other said image data stored in said memory; and

10 said selection prohibiting controller prohibits selecting a two-side print mode through said operation panel when it is determined that said memory stores said image data different in frame size from other said image data stored in said memory, said two-side print mode being provided for printing said image data stored in said memory on both sides of a sheet.

16. The image forming apparatus according to claim 13, wherein:

5 said state decision controller determines whether said image data stored in said memory all have a same frame size; and

 said selection prohibiting controller prohibits selecting an economy print mode through said operation

panel when it is determined that said image data stored in said memory all have a same frame size, said economy print mode being provided for printing said image data of a plurality of frames on one same side of a sheet.

17. An image forming apparatus operable in a plurality of print modes, comprising:

a memory for storing a print job containing image data of no less than one frame;

5 a print-job selector for selecting one of said print jobs stored in said memory;

state decision controller determines a state of said image data contained in said print job selected by said print-job selector;

10 a printer for printing said image data contained in said print job selected by said print-job selector;

a display for displaying an operating state of said image forming apparatus; and

15 a display controller for displaying on said display an operable print mode of said plurality of print modes according to the state of said image data.

18. The image forming apparatus according to claim 17, wherein said state decision controller determines a length of a frame of said image data in a predetermined direction.

19. The image forming apparatus according to claim 18,
further comprising a finisher for stapling sheets printed
by said printer, wherein:

said frame-length decision controller determines
5 whether said image data contained in said print job
selected by said print-job selector all have a same frame
length in said determined direction; and

10 said display controller displays a staple print mode
on said display when it is determined that said image data
contained in said print job all have a same frame length
in said predetermined direction, said staple print mode
being provided so that said finisher provides a staple
processing.

20. The image forming apparatus according to claim 17,
wherein said state decision controller determines a frame
size of said image data.

21. The image forming apparatus according to claim 20,
wherein:

said frame-size decision controller determines
whether said image data contained in said print job
5 selected by said print-job selector all have a same frame
size; and

said display controller displays a two-side print

mode on said display when it is determined that said image data contained in said print job all have a same size,
10 said two-side print mode being provided for printing said image data on both sides of a sheet.

22. The image forming apparatus according to claim 20,
wherein:

5 said frame-size decision controller determines whether said image data contained in said print job selected by said print-job selector all have a same frame size; and

said display controller displays on said display an economy print mode for printing said image data of a plurality of frames contained in said print job.

23. An image forming apparatus operable in a plurality of print modes, comprising:

a memory for storing a print job containing image data of no less than one frame;

5 print-job selector for selecting one of said print jobs stored in said memory;

state decision controller for determining a state of said image data contained in said print job selected by said print-job selector;

10 a printer for printing said image data contained in

15 said print job selected by said print-job selector;
 an operation panel for selecting any of said
 plurality of print modes; and
 a selection prohibiting controller for prohibiting
 selecting an inoperable print mode of said plurality of
 print modes through said operation panel according to the
 state of said image data contained in said print job.

24. The image forming apparatus according to claim 23,
further comprising a finisher for stapling sheets printed
by said printer, wherein:

5 said state decision controller determines whether
 said print job selected by said print-job selector
 contains said image data different in frame size from
 other said image data contained in said selected print
 job; and
 said selection prohibiting controller prohibits
10 selecting a staple print mode through said operation panel
 when it is determined that said print job selected by said
 print-job selector includes said image data different in
 frame size from other said image data contained in said
 selected print job, said staple print mode being provided
15 so that said finisher provides a staple processing.

25. The image forming apparatus according to claim 23,
wherein:

5 said state decision controller determines whether
 said print job selected by said print-selector includes
 said image data different in frame size from other said
 image data contained in said selected print job; and
 said selection prohibiting controller prohibits
 selecting a two-side print mode through said operation
 panel when it is determined that said print job selected
10 by said print-job selector includes said image data
 different in frame size from other said image data
 contained in said selected print job, said two-side print
 mode being provided for printing said image data on both
 sides of a sheet.

26. The image forming apparatus according to claim 23,
wherein:

5 said state decision controller determines whether
 said image data contained in said print job selected by
 said print-job selector all have a same frame size; and
 said selection prohibiting controller prohibits
 selecting an economy print mode through said operation
 panel when it is determined that said image data contained
 in said print job selected by said print-job selector all
10 have a same frame size, said economy print mode being
 provided for printing said image data of a plurality of
 frames on same one side of a sheet.

ABSTRACT OF THE DISCLOSURE

A user-friendly, image forming apparatus capable of reducing operation errors by users provides a permission to change a print mode to the staple print mode when the 5 device is placed in the original mixed mode and the image data of originals all have a same length in the main scanning direction. When the image data also have a same length in a subscanning direction, the apparatus provides a permission to change the current print mode to the 10 economy print mode and the two-side print mode. Only a print mode which is permitted as an optional print mode is displayed on a screen on the liquid crystal touch panel.

DECLARATION AND POWER OF ATTORNEY

As the below-named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name;

I believe that I am the original, first and sole inventor of the subject matter which is claimed and for which a patent is sought on the invention or discovery entitled

IMAGE FORMING APPARATUS CAPABLE OF IMAGE FORMATION
IN A PLURALITY OF MODES

the specification of which is attached hereto:

I have reviewed and understand the contents of the above-identified specification, including the claims; and

I acknowledge the duty to disclose to the Patent and Trademark Office all information known to me which is material to patentability as defined in 37 C.F.R. § 1.56.

I hereby claim foreign priority benefits under 35 U.S.C. § 119/365 of any foreign application for patent or inventor's certificate as listed below or of any PCT international application, designating at least one country other than the United States of America, as listed below and have also identified below any foreign application for patent or inventor's certificate or any PCT international application, designating at least one country other than the United States of America, directed to said invention or discovery and having a filing date before that of the applications on which priority is claimed:

<u>NUMBER</u>	<u>COUNTRY</u>	<u>DATE FILED</u>	<u>PRIORITY CLAIMED</u>
			(Yes) (No)
9-057684 (P)	Japan	12/March/1997	X

I hereby appoint:

Dale B. Nixon, Reg. No. 28,454
 William R. Gustavson, Reg. No. 29,160
 David L. Hitchcock, Reg. No. 30,067
 Roger N. Chauza, Reg. No. 29,753
 Eugenia S. Hansen, Reg. No. 31,966
 James W. Williams, Reg. No. 20,047
 Elisabeth A. Evert, Reg. No. 34,156

all of the firm of SIDLEY & AUSTIN, my attorneys with full power of substitution and revocation, to prosecute this application and to transact all business in the United States Patent and Trademark Office connected therewith, and to file and prosecute any international patent applications filed thereon before any international authorities under the Patent Cooperation Treaty.
